

## DISCRIPTION

The LV2842YLVDCCR is 40V, 1A buck converter with an integrated 400 mΩ high-side MOSFET and 200 mΩ low-side MOSFET. The LV2842YLVDCCR has wide input range from 4.6V to 40V, the LV2842YLVDCCR is suitable for variable applications which is from unregulated sources, like industrial or automotive applications. The device adopts peak current mode and has the fixed switching frequency. The quiescent current of this device is 80uA in sleep mode and the shutdown current is 1uA, making it suitable for battery-powered system. The device integrates protections, like cycle-by-cycle current limit, thermal shutdown, short-circuit and over-voltage protection. It's available in a cost effective TSOT23-6L package.

## APPLICATIONS

- Industrial 24V Distributed Power Bus
- Power meter
- Elevator, PLC, Servo
- Automatic Control

## TYPICAL APPLICATION

## FEATURES

- Wide Input Range: 4.6V-40V
- Up to 1A Continuous Output Current
- 0.81V  $\pm$  2.5% Feedback Reference Voltage
- Integrated 400mΩ High-Side and 200mΩ Low-Side Power MOSFETs
- Fixed Frequency 1MHz
- Pulse Skipping Mode (PSM) at Light Load
- 80uA Quiescent Current in Sleep Mode
- 80ns Minimum On-time
- 1ms Internal Soft-start Time
- Over-Current Protection and Hiccup

## PIN CONFIGURATION AND FUNCTIONS

## DISCRIPTION

### Overview

The LV2842YLVDDCR is a 40V, 1A buck converter with an integrated 400 mΩ high-side MOSFET and 200 mΩ low-side MOSFET. With a wide input range from 4.6V to 40V, the device adopts peak current mode and supports a fixed 1MHz switching frequency to minimize off-chip components. The LV2842YLVDDCR features an internal 1ms soft-start time.

The quiescent current of this device is 80uA in sleep mode and the shutdown current is 1uA. The LV2842YLVDDCR features an internal 1ms soft-start time. The device has a default input start-up voltage of 4.3V with 450mV hysteresis. The EN pin is a high-voltage pin with a precision threshold that can be used to adjust the input voltage lockout thresholds with two external resistors to meet accurate higher UVLO system requirements. Floating EN pin enables the device. Connecting EN pin to VIN directly starts up the device automatically.

The device integrates protections, like cycle-by-cycle current limit, thermal shutdown protection, output over-voltage protection and output short circuit protection and input voltage under-voltage protection. The device also supports monolithic startup with pre-biased output condition.

### Peak Current Mode Control

The LV2842YLVDDCR employs fixed frequency peak current mode control. An internal clock initiates turning on the integrated high-side power MOSFET in each cycle, then inductor current rises linearly. When the current through high-side MOSFET reaches the threshold level set by the internal compensation voltage of the internal error amplifier, the high-side MOSFET turns off. When the high-side MOSFET turns off, the inductor current discharges through the low-side MOSFET till the next clock cycle begins.

The integrated error amplifier and the internal compensation builds up the feedback loop to regulate the output voltage to the reference. The error amplifier comparing the voltage of the FB pin with an internal reference voltage of 0.81V. The load current increasement reduces the feedback voltage which is relative to a voltage raise of the error amplifier output till the average inductor current matches the increased load current.

The device also integrates an internal slope compensation circuitry to prevent sub-harmonic oscillation when duty cycle is greater than 50% for a fixed frequency peak current mode control.

### Pulse Skipping Mode (PSM)

The LV2842YLVDDCR operates in Pulse Skipping Mode (PSM) with light load current to improve efficiency. A decrease of the load current leads an increasement in the feedback voltage which yields down the compensation voltage. When the compensation voltage drops to a low clamp threshold, the PSM is triggered.

During the skipping period, the discharge of output capacitor leads the output voltage drop which makes the FB voltage decay. Once the FB voltage drops lower than the reference voltage and the compensation voltage rises above the low clamp threshold, the integrated high-side MOSFET turns on in next clock pulse. After several switching cycles with typical 0.2A peak inductor current, the internal compensation voltage drops and is clamped again and pulse skipping mode repeats if the output continues light loaded.

This PSM helps achieving higher efficiency by skipping cycles to reduce switching power loss and gate drive charging loss. Regarding to improve efficiency further, the quiescent current is 80uA during skipping period with no switching.

## VIN Power

The LV2842YLVDDCR is designed to operate from an input voltage supply range between 4.6V to 40V, at least 0.1uF and 10uF decoupling ceramic cap are recommended to bypass the supply noise.

## Under Voltage Lockout Threshold and Enable

The EN pin of LV2842YLVDDCR is a high voltage pin which can be connected to VIN directly to start-up the device. The LV2842YLVDDCR is enabled when the EN pin voltage higher than the enable threshold of 1.25V and disabled when the EN pin voltage lower than 1.1V. Grace to the internal 1.0uA pull-up current, the device is default enabled when the EN pin floats.

The Under Voltage Lock Out (UVLO) default startup threshold is typical 4.3V with VIN rising and shutdown threshold is 3.85V with VIN falling. The more accurate UVLO threshold can be programmed through the precision enable threshold of EN pin. Connect an external resistor divider (RL and RH) shown in Figure 8 from VIN to EN. The UVLO rising and falling threshold can be calculated by Equation 1 and Equation 2 respectively.

$$R_H = \frac{V_{rise} - 1.14 * V_{fall}}{1.14 * 4.5\mu A - 1.5\mu A} \quad (1)$$

$$R_L = \frac{1.25V}{\frac{V_{rise} - 1.25V}{R_H} + 1.5\mu A} \quad (2)$$

where

- $V_{rise}$  is rising threshold of Vin UVLO
- $V_{fall}$  is falling threshold of Vin UVLO

**Figure 8. System UVLO by EN divider**

## Bootstrap Voltage Regulator

An external bootstrap capacitor between BOOT pin and SW pin powers floating high-side power MOSFET gate driver. The bootstrap capacitor voltage is charged from an integrated voltage regulator when high-side power MOSFET is off.

The floating supply (BOOT to SW) UVLO threshold is 2.7V rising and hysteresis of 350mV. When the converter operates with high duty cycle or prolongs in sleep mode for certain long time, the required time interval to recharging bootstrap capacitor is too long to keep the voltage at bootstrap capacitor sufficient. When the voltage across bootstrap capacitor drops below 2.35V, BOOT UVLO occurs.

## Output Voltage

The LV2842YLVDDCR regulates the internal reference voltage at 0.81V with  $\pm 1\%$  tolerance over the operating temperature and voltage range.

The output voltage is set by a resistor divider from the output node to the FB pin. It is recommended to use 1% tolerance or better resistors. Use Equation 3 to calculate resistance of resistor dividers. To improve efficiency at light loads, larger value resistors are recommended. However, if the value is higher, the regulator will be more noise sensitive. RFB\_BOT in the range of 10k $\Omega$  to 100k $\Omega$  is recommended for most application.

$$R_{FB\_TOP} = \left( \frac{V_{OUT}}{0.81V} - 1 \right) * R_{FB\_BOT} \quad (3)$$

where

- R<sub>FB\_TOP</sub> is the resistor connecting the output to the FB pin.
- R<sub>FB\_BOT</sub> is the resistor connecting the FB pin to the ground.

## Overcurrent and Short Circuit Protection

The LV2842YLVDDCR adopts the peak current mode control. In the overcurrent momentum, the output voltage is yield down by heavy load and the error amplifier drives the compensation voltage high to increase the switching current. As the error amplifier output increases, it will be clamped internally, and the high-side current is clamped by a maximum peak current threshold. The peak current threshold is constant over the full duty cycle range.

When the output overcurrent or short circuit occurs, the device will trigger a cycle-by-cycle peak current clamping and frequency foldback by skipping pulse. This will lead more time for the inductor current to ramp down. Furthermore, a lower switching frequency contributes on lower switching loss, avoids overheating and other potential damages.

## Overvoltage Protection

The LV2842YLVDDCR implements the overvoltage protection (OVP) circuitry to minimize output voltage overshoot during load transient, recovering from output fault condition or light load transient. When the FB pin voltage reaches the rising OVP threshold which is typically 109% of  $V_{REF}$ , the high-side MOSFET will be turned off immediately which make the device under OVP. When the FB pin voltage drops below the falling OVP threshold, the high-side MOSFET is turned on and resumed normal operation. The falling OVP threshold is typically 105% of  $V_{REF}$ .

## Thermal Shutdown

The LV2842YLVDDCR features an internal thermal shutdown circuit to protect the device from the damage during excessive heat and power dissipation conditions. The thermal shutdown circuit will be asserted when the junction temperature exceeds typically 170°C. When the junction temperature falls below 140°C, the device restarts with internal soft start phase.

## APPLICATION INFORMATION

### Typical Application

**Table 1. Design Parameters**

| Design Parameters                     | Example Value      |
|---------------------------------------|--------------------|
| Input Voltage                         | 24V typical, 6~36V |
| Output Voltage                        | 5V                 |
| Output Current                        | 1A                 |
| Output voltage ripple (peak to peak)  | <50mV              |
| Overshoot/Undershoot range (0.1~0.9A) | <5%                |
| Switching Frequency                   | 1MHz               |

## Set Output Voltage

The LV2842YLVDDCR output voltage can be easily set up using a resistor divider network R1 and R2 as shown in the typical application circuit Figure 9. Use Equation (4) to calculate the resistor divider values.

$$R1 = \frac{(V_{OUT} - 0.8) \times R2}{0.8} \quad (4)$$

In this design example the Vout is 5V. Set the resistor R2 value to be approximately 20k.

$$R1 = \frac{(V_{OUT} - 0.8) \times R2}{0.8} = \frac{(5 - 0.8) \times 20k\Omega}{0.8} = 105 k\Omega$$

Slightly increasing or decreasing R1 to a closest available resistance, the 105kΩ is selected.

## Input Capacitor Selection

For good input voltage filtering, choose low-ESR ceramic capacitors. A X7R ceramic capacitor 4.7μF to 10μF is recommended for the decoupling capacitor and a 0.1μF ceramic bypass capacitor is recommended to be placed as close as possible to the VIN pin. These capacitors must be rated for 50V.

For this design, one 4.7μF X7R capacitors and one 0.1μF capacitor rated 50V is recommended.

The input voltage ripple can be calculated by using Equation (5) to calculate the input voltage ripple:

$$\Delta V_{IN} = \frac{I_{OUT}}{C_{IN} \times f_{SW}} \times \frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) = \frac{1A}{4.7\mu F \times 1000k} \times \frac{5V}{24V} \times \left(1 - \frac{5V}{24V}\right) = 35mV \quad (5)$$

Where:

- C<sub>IN</sub> is the input capacitor value
- f<sub>sw</sub> is the converter switching frequency
- I<sub>OUT</sub> is the maximum load current

## Inductor Selection

The performance of inductor affects the power supply's steady state operation, transient behavior, loop stability, and buck converter efficiency. The critical parameters of inductor is the inductance, the DC resistance (DCR), the saturation current and the RMS current.

Use following equation to the minimum inductance:

$$L_{MIN} = \frac{V_{OUT} \times (V_{INMAX} - V_{OUT})}{V_{INMAX} \times K_{IND} \times I_{OUT} \times f_{SW}} \quad (6)$$

Where

- $V_{OUT}$  is output voltage
- $K_{IND}$  is the Ripple Ratio of the inductor ripple current ( $\Delta I_L/I_{OUT}$ ), 0.3 is recommended here
- $V_{INMAX}$  is the maximum input voltage
- $f_{SW}$  is the converter switching frequency
- $I_{OUT}$  is the output current

In this design example:

$$L > L_{MIN} = \frac{V_{OUT} \times (V_{INMAX} - V_{OUT})}{V_{INMAX} \times K_{IND} \times I_{OUT} \times f_{SW}} = \frac{5V \times (40V - 5V)}{40V \times 0.3 \times 1A \times 1MHz} = 14.6 \mu H$$

15uH is selected in the design example. Generally, the Inductor values can have  $\pm 20\%$  or even  $\pm 30\%$  tolerance with no current bias. When the inductor current approaches saturation level, its inductance can decrease 20% to 35% from the value at 0A current depending on how the inductor vendor defines saturation. When selecting an inductor, choose its rated current especially the saturation current larger than its peak current during the operation.

## Output Capacitor

The output capacitor must be chosen carefully with the reason that this capacitor value determines the regulator pole, the output voltage ripple, and how the regulator responds to a large change in load current. Generally, choose a low-ESR output capacitor like a ceramic capacitor from X5R or X7R family to get small output voltage ripple.

From the required output voltage ripple ( $< 5mV$ ), use the Equation 7 to calculate the minimum required effective capacitance,  $C_{OUT}$ .

$$C_{OUT} > \frac{\Delta I_{LPP}}{8 \times V_{OUT\_Ripple} \times f_{SW}} = \frac{K_{IND} \times I_{OUT}}{8 \times V_{OUT\_Ripple} \times f_{SW}} \quad (7)$$

The allowed maximum ESR of the output capacitor is calculated by the equation 8.

$$R_{ESR} < \frac{V_{OUT\_Ripple}}{K_{IND} \times I_{OUT}} \quad (8)$$

Where

- $V_{OUT\_Ripple}$  is output voltage ripple caused by charging and discharging of the output capacitor.
- $K_{IND}$  is the Ripple Ratio of the inductor ripple current ( $\Delta I_L/I_{OUT}$ ), 0.3 is recommended here
- $I_{OUT}$  is the maximum output current
- $f_{SW}$  is the converter switching frequency.

In this design,  $V_{OUT\_Ripple}$  is smaller than 5mV,  $f_{SW}$  is 1000kHz,  $I_{OUT}$  is 1A and  $K_{IND}$  is 0.3:

$$C_{OUT} > \frac{0.3 \times 1A}{8 \times 5mV \times 1000k} = 7.5 \mu F$$

$$R_{ESR} < \frac{5mV}{0.3 \times 1A} = 16.7 m\Omega$$

Therefore, a X7R capacitor of 22 $\mu$ F with 16V DC rating and 15m $\Omega$  ESR is selected

## Bootstrap Capacitor

For proper operation of the device, a 0.1 $\mu$ F ceramic capacitor of X5R or X7R must be placed between the SW pin to the BOOT pin. The DC rating of this capacitor is must be 10V or higher voltage level.

## Application Curves

Figure 10 through Figure 25 apply to the circuit of Figure 9.  $V_{IN} = 24\text{ V}$ ,  $T_A = 25^\circ\text{C}$  unless otherwise specified

## Layout Guideline and Layout Example

Layout is critical for proper operation. Please follow the layout guidelines.

1. The power ground is very critical. The power trace should take lowest impedance as possible and the ground area should be sufficient to optimize thermal, 8mil max thermal via recommended.
2. Place the bypass input capacitor with low ESR as close as possible to the VIN pin and GND. The bypassing loop from VIN terminal to the GND should be as short as possible.
3. The inductor should be located as close as possible to the SW pin for reducing magnetic and electrostatic noise.
4. The feedback resistor divider should be placed close to the FB pin.
5. The ground connected to the input capacitors and output capacitors should be tied to the system ground plane in only one spot to minimize conducted noise to the system ground plane.
