General Description

The SY8089 and SY8089A are high-efficiency, high frequency synchronous step-down DC-DC regulator IC capable of delivering up to 2A output current. The SY8089 and SY8089A operate over a wide input voltage range from 2.7V to 5.5V and integrate main switch and synchronous switch with very low $R_{DS(ON)}$ to minimize the conduction loss.

Low output voltage ripple and small external inductor and capacitor sizes are achieved with greater than 1MHz switching frequency.

SY8089 integrates short circuit and over-voltage latch off protection.

Temperature Range: -40°C to 85°C

Features

- Low $R_{DS(ON)}$ for internal switches (top/bottom): 110mΩ/80mΩ
- 2.7-5.5V input voltage range
- 2A continuous, 3A peak load current capability
- 1MHz switching frequency minimizes the external components
- Internal softstart limits the inrush current
- Reliable short circuit protection:
  - SY8089: Latch off protection
  - SY8089A: Hiccup mode protection
- Reliable over-voltage protection:
  - SY8089: Latch off protection
  - SY8089A: No latch off protection
- 100% dropout operation
- RoHS Compliant and Halogen Free
- Compact package: SOT23-5

Applications

- LCD TV
- Set Top Box
- Net PC
- Mini-Notebook PC
- Access Point Router

**Note 1:** Stresses beyond the “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only. Functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**Note 2:** Test condition: Device mounted on 2” x 2” FR-4 substrate PCB, 2oz copper, with minimum recommended pad on top layer and thermal vias to bottom layer ground plane.

**Note 3:** The device is not guaranteed to function outside its operating conditions.
Typical Performance Characteristics

Efficiency vs. Load Current

Time (40μs/Div)
Operation Principle
SY8089 is a synchronous buck regulator IC that integrates the PWM control, top and bottom switches on the same die to minimize the switching transition loss and conduction loss. With ultra low $R_{DS(ON)}$ power switches and proprietary PWM control, this regulator IC can achieve the highest efficiency and the highest switch frequency simultaneously to minimize the external inductor and capacitor size, and thus achieving the minimum solution footprint.

Short Circuit Protection
(SY8089) After the soft start is over, if the output voltage falls below 40% of the regulation level, IC will turn off both power switches, entering short circuit protection. It will remain in this state until the IN or EN voltage is recycled.

(SY8089A) The frequency is folded back to about 30% of the nominal frequency and the current limit is folded back to 3.0A to prevent the inductor current from runaway and to reduce the power dissipation of the IC under short circuit conditions.

Over-voltage Protection
If the output voltage exceeds 120% of the regulation level for more than 20µs, IC will turn off both power switches and turn on the discharge switch, entering over-voltage protection. It will remain in this state until IN or EN voltage is recycled.

Applications Information
Because of the high integration in the SY8089 IC, the application circuit based on this regulator IC is rather simple. Only input capacitor $C_{IN}$, output capacitor $C_{OUT}$, output inductor $L$ and feedback resistors ($R_1$ and $R_2$) need to be selected for the targeted applications specifications.

Feedback resistor dividers $R_1$ and $R_2$:
Choose $R_1$ and $R_2$ to program the proper output voltage. To minimize the power consumption under light loads, it is desirable to choose large resistance values for both $R_1$ and $R_2$. A value of between 10k and 1M is highly recommended for both resistors. If $V_{OUT}$ is 1.8V, $R_1=100k$ is chosen, then $R_2$ can be calculated to be 50k:
$$R_2 = \frac{0.6V}{V_{OUT}-0.6V} \times R_1(\Omega).$$

Input capacitor $C_{IN}$:
This ripple current through input capacitor is calculated as:
$$I_{CIN,RMS} = I_{OUT} \times \sqrt{D(1-D)}.$$
This formula has a maximum at $V_{IN}=2V_{OUT}$ condition, where $I_{CIN,RMS}=I_{OUT}/2$. This simple worst-case condition is commonly used for DC/DC design.

With the maximum load current at 2.0A. A typical X5R or better grade ceramic capacitor with 6.3V rating and more than 22µF capacitor can handle this ripple current well. To minimize the potential noise problem, ceramic capacitor should really be placed close to the IN and GND pins. Care should be taken to minimize the loop area formed by $C_{IN}$, and IN/GND pins.

Output capacitor $C_{OUT}$:
The output capacitor is selected to handle the output ripple noise requirements. Both steady state ripple and transient requirements must be taken into consideration when selecting this capacitor. For the best performance, it is recommended to use X5R or better grade ceramic capacitor with 6.3V rating and greater than 22µF capacitance.

Output inductor $L$:
There are several considerations in choosing this inductor.
1) Choose the inductance to provide the desired ripple current. It is suggested to choose the ripple current to be about 40% of the maximum output current. The inductance is calculated as:
$$L = \frac{V_{OUT}(1-V_{OUT}/V_{IN,MAX})}{F_{SW} \times I_{OUT,MAX} \times 40\%}.$$
where $F_{SW}$ is the switching frequency and $I_{OUT,MAX}$ is the maximum load current.
The SY8089 regulator IC is quite tolerant of different ripple current amplitude. Consequently, the final choice...
of inductance can be slightly off the calculation value without significantly impacting the performance.

2) The saturation current rating of the inductor must be selected to be greater than the peak inductor current under full load conditions.

\[ I_{SAT, MIN} > I_{OUT, MAX} + \frac{V_{OUT}(1-V_{IN, MAX})}{2 \cdot F_{SW} \cdot L} \]

3) The DCR of the inductor and the core loss at the switching frequency must be low enough to achieve the desired efficiency requirement. It is desirable to choose an inductor with DCR < 50mΩ to achieve a good overall efficiency.

Enable Operation

Pulling the EN pin low (<0.4V) will shut down the device. During shut down mode, the SY8089 shutdown current drops to lower than 0.1uA. Driving the EN pin high (>1.5V) will turn on the IC again.

Load Transient Considerations:

The SY8089 regulator IC integrates the compensation components to achieve good stability and fast transient responses. In some applications, adding a 22pF ceramic cap in parallel with R1 may further speed up the load transient responses and is thus recommended for applications with large load transient step requirements.

Layout Design:

The layout design of SY8089 regulator is relatively simple. For the best efficiency and minimum noise problems, we should place the following components close to the IC: C_IN, L, R1 and R2.

1) It is desirable to maximize the PCB copper area connecting to GND pin to achieve the best thermal and noise performance. If the board space allowed, a ground plane is highly desirable.
2) C_IN must be close to Pins IN and GND. The loop area formed by C_IN and GND must be minimized.
3) The PCB copper area associated with LX pin must be minimized to avoid the potential noise problem.
4) The components R1, R2, and the trace connecting to the FB pin must NOT be adjacent to the LX net on the PCB layout to avoid the noise problem.
5) If the system chip interfacing with the EN pin has a high impedance state at shutdown mode and the IN pin is connected directly to a power source such as a LiIon battery, it is desirable to add a pull down 1MΩ resistor between the EN and GND pins to prevent the noise from falsely turning on the regulator at shutdown mode.
Recommended Pad Layout
